

# **The Use of Modeling and Simulation in Regulatory Decisions and Reviews**

**Jeffry Florian, Ph.D.  
Division of Pharmacometrics  
Office of Clinical Pharmacology  
OTS/CDER, FDA**

# Clinical Pharmacology: The Past

## The Future

# Model Based Drug Development

**“The concept of model-based drug development, in which pharmaco-statistical models of drug efficacy and safety are developed from preclinical and available clinical data, offers an important approach to improving drug development knowledge management and development decision making.”**

***Lewis B. Sheiner, “Learning vs Confirming in Clinical Drug Development”, Clin. Pharmacol. Ther., 1997, 61:275-291.***

# Office of Clinical Pharmacology Review Deliverables

- **Does the dose/exposure response support efficacy of the product?**
- **Is the appropriate dose or dosing regimen identified based on dose/exposure response for both safety and efficacy?**
- **Is the proposed dose individualization scheme reasonable?**
- **Are the metabolic pathways and potential for drug-drug interactions adequately characterized?**
- **Were the relevant special population studies conducted?**
- **Are there any “show stoppers” (i.e. issues that could preclude approval) regarding the above key components or other aspects of the application?**

# Pharmacometrics Scope:

# Tasks

# Case Study 1: Bridging Interferon Responsiveness from HCV Trials

*(Jiang Liu and Jeffry Florian)*

Clinical Pharmacology Review of Boceprevir and Telaprevir, 2011

<http://www.fda.gov/downloads/AdvisoryCommittees/CommitteesMeetingMaterials/Drugs/AntiviralDrugsAdvisoryCommittee/UCM254087.pdf>

<http://www.fda.gov/downloads/AdvisoryCommittees/CommitteesMeetingMaterials/Drugs/AntiviralDrugsAdvisoryCommittee/UCM254076.pdf>

**Two new HCV therapies** were submitted to the FDA in late 2010. Both submissions were characterized by drastically **different** drug development **programs**.

| REGISTRATIONAL TRIAL DESIGNS | BOCEPREVIR               | TELAPREVIR                                                 |
|------------------------------|--------------------------|------------------------------------------------------------|
| Lead-in Phase                | YES                      | NO                                                         |
| Response Guided Therapy      | All trials               | Only treatment-naïve patients                              |
| P/R-nonresponders trial      | Excludes null responders | Include relapsers, partial responders, and null responders |

**Two programs, same story**

## “Bridging” Observations Through **Interferon Responsiveness**

- Similar response with **first or second round** of P/R treatment
  - Data for P/R-nonresponders are “**bridged**” with data from treatment-naïve subjects
- Previous P/R-nonresponders are represented within treatment-naïve subjects
- P/R treatment for HCV is unlike HIV treatment which frequently leads to **resistance** and does not yield **similar virologic response** on subsequent courses of treatment

**P/R-nonresponders (P/R-nonR) are represented within treatment-naïve (TN) subjects. Decline in HCV RNA at week 4 ‘bridges’ interferon response between treatment populations.**

# Antiviral Information Management System (AIMS) Database to Leverage Prior Data

\* 799- P/R-nonR

\* 3068-TN

# Similar Virologic Response at Week 4 with First or Second PR treatment (pooled analysis)

## Telaprevir: Is RGT for Relapse Subjects Acceptable?

| Population                       | eRVR          | Evidence to support RGT                                                                                                                                                                                                                                    |
|----------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Treatment-Naïve                  | T12/PR24      | Study 111                                                                                                                                                                                                                                                  |
| P/R-nonresponders: Prior Relapse | T12/PR24<br>? | <input type="checkbox"/> <b>Cross-trial</b> comparison of data from Phase 2 and 3 trials<br><br><input type="checkbox"/> <b>Bridging</b> data from treatment naïve population<br><br><input type="checkbox"/> <b>Viral Dynamics</b> (Applicant's analysis) |

## Response Rates in Relapse Subjects with eRVR Across Phase 2 and 3 Trials

Relapse subjects with eRVR achieved >90% SVR irrespective of 24 or 48 weeks of PR treatment

## Treatment-Naïve *future* Relapse and P/R-nonresponder (Prior) Relapse Subjects demonstrate similar Virologic Response at Week 4 with First or Second PR treatment

| Population                  | Study | Week 4 Decline in log <sub>10</sub> Viral Load |        |
|-----------------------------|-------|------------------------------------------------|--------|
|                             |       | Mean                                           | Median |
| <i>future</i> Relapse (EOS) | 108   | -2.8                                           | -2.9   |
| Prior Relapse (Baseline)    | C216  | -2.7                                           | -2.4   |

The range of week 4 response (not just mean) is also similar for all comparisons (*future* relapse vs prior relapse; *future* partial vs prior partial; *future* null vs prior null)

# RGT is Recommended for *future* Relapse Subjects Among Treatment-Naïve Population

## Study 108

PR Response Rate

Telaprevir Response Rate

T12/PR24

T12/PR48

## Prior P/R-nonresponders are Represented within Treatment-naïve Subjects

| Population | % Response SOC  | % Response TVR (within group) | %SVR (overall) |
|------------|-----------------|-------------------------------|----------------|
| Responders | 44 <sup>a</sup> |                               | —              |
| Relapsers  | 18 <sup>a</sup> |                               | —              |
| Partial    | 19 <sup>a</sup> |                               | —              |
| Null       | 9 <sup>a</sup>  |                               | —              |

a- P/R (control) arm from study in untreated subjects (108)

## Summary of Case Study 1

- Similar response with first or second round of PR treatment
  - Data for P/R-nonresponders subjects are “bridged” with data from treatment-naïve subjects
- eRVR on current therapy appears to be more important predictor of SVR than previous response to PR
- Prior relapse subjects with eRVR achieve >90% SVR (Cross-trial comparison) irrespective of 24 or 48 weeks of PR treatment

## **Case Study 2: PK-Bridging Approach to Approve IV Nexium® and Select Appropriate Doses In Pediatrics**

**Clinical Pharmacology Review of Nexium IV, 2011**

<http://www.accessdata.fda.gov/scripts/cder/drugsatfda/>

# Pharmacometrics can Streamline Pediatric Drug Development

## IV Nexium (esomeprazole)

- Regulatory History:
  - Oral Nexium is approved in pediatrics & adults
  - IV Nexium is approved in Adults
- Application for Pediatric Nexium IV
  - Pop PK & Safety Data: 50 pediatrics (0 – 17 yr)
  - Pediatric PK were compared to Adult PK
- Dose Selection:
  - Dosing regimen adjusted so AUC and  $C_{\max}$  values match adult data

# Exposure-Response is Similar Between Adults and Children

# Pediatric Dosing Recommendations

## Proposed Dosing

| <u>Age Group</u> | <u>Treatment of erosive reflux esophagitis</u>               | <u>Treatment of Symptomatic GERD</u> |
|------------------|--------------------------------------------------------------|--------------------------------------|
| 1 – 11 yr        | Weight < 20kg: 10 mg QD<br>Weight ≥ 20 kg: 10 mg or 20 mg QD | 10 mg QD                             |
| 12-17 yr         | 40 mg QD                                                     | 20 mg QD                             |

3-min injection,  
10-30 min Infusion

## FDA Approved Dosing

| <u>Weight Range</u> | <u>GERD:</u><br>• Symptomatic GERD<br>• Erosive Esophagitis |
|---------------------|-------------------------------------------------------------|
| < 55 kg             | 10 mg                                                       |
| > 55 kg             | 20 mg                                                       |

10-30 min infusion

# Esomeprazole CL Increases with Body Weight

# AUCs Values in Pediatrics ~ Adults

# $C_{\max}$ Values in Pediatrics > Adults for 3 min Injection

## 30-min Infusion $C_{\max}$ Values in Pediatrics ~ Adults

- 10-min infusion:  $C_{\max} < 40$  mg in adults (13.5 nM/mL)
- Exposures higher than 20 mg dose for only 2 minutes

## Summary of Case Study 2

### Value to Drug Development

- Approval of drug without additional safety and efficacy trials
- Approval of dosing regimen not studied directly in clinical trials

### Value to Public Health

- Method provides more consistent exposures in pediatrics

# Case Study 3: PK/PD Risk-Benefit Assessment for Mirebegron *(Jiang Liu and Raj Madabushi)*

Clinical Pharmacology Review Mirabegron, 2012

[http://www.accessdata.fda.gov/drugsatfda\\_docs/nda/2012/202611Orig1s000ClinPharmR.pdf](http://www.accessdata.fda.gov/drugsatfda_docs/nda/2012/202611Orig1s000ClinPharmR.pdf)

# Pivotal trials for mirabegron

Phase 3 trials Phase 2b

| Study                      | Primary efficacy endpoint                                                                             | Treatment                                                       | No. of subj. |
|----------------------------|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|--------------|
| 178-CL-044<br>(Euro)       | co-primary efficacy endpoints:                                                                        | Placebo, mirabegron 25, 50, 100, or 200 mg, or tolterodine 4 mg | 928          |
| 178-CL-046<br>(Euro & Aus) | 1) change from baseline to final visit (Week 12) in mean number of incontinence episodes per 24 hours | Placebo, mirabegron 50 or 100 mg, or tolterodine 4 mg           | 1987         |
| 178-CL-047<br>(Can & US)   | 2) change from baseline to final visit in mean number of <u>micturitions</u> per 24 hours             | Placebo, mirabegron 50 or 100 mg                                | 1329         |
| 178-CL-074<br>(Euro & NA)  |                                                                                                       | Placebo, mirabegron 25 or 50 mg                                 | 1306         |

# Doses of 25 mg or higher had similar time-course responses for primary endpoints

# Increase in SBP<sup>†</sup> is exposure dependent

# Dose Dependent Increase in SBP Observed in Phase III

*Changes greater than 1.2 mmHg are ruled out*

Pooled 12-week Phase III Studies

# CVD Risk Assessment Approach

- A continuous multivariate risk function\* used to predict 10-year risk of developing Cardiovascular Disease (CVD)
- CVD – Coronary Heart Disease, Cerebrovascular Events, Peripheral Arterial Disease, or Heart Failure
- Risk Predictors: Sex, Age, **Systolic Blood Pressure**, Treatment for Hypertension, Diabetes Status, Total and High-Density Lipoprotein Cholesterol, and Smoking Status

*\*General Cardiovascular Risk Profile for Use in Primary Care: The Framingham Heart Study – D'Agostino et al. Circulation 2008;117;743-753*

# CVD Risk Assessment Approach

## Summary of Available CVD Risk Predictors<sup>†</sup> at Baseline in Pooled 12-week Phase III Studies

| Patient Characteristics       | Placebo<br>N = 1329 | Mirabegron 50 mg<br>N = 1327 |
|-------------------------------|---------------------|------------------------------|
| Age, yrs (Mean, [SD])         | 59 (13)             | 60 (13)                      |
| AM SBP, mmHg (Mean, [SD])     | 126 (17)            | 126 (17)                     |
| Gender, M/F                   | 363/966             | 383/944                      |
| Antihypertensive Treatment, % | 40                  | 39                           |
| Diabetes Status, %            | 8                   | 9                            |
| 10-year CVD Risk (Median)     | 10%                 | 11%                          |

<sup>†</sup>Total and High-Density Lipoprotein Cholesterol, and Smoking Status not collected in Phase III programs. Imputed based on age and sex

## Summary of Available CVD Risk Predictors<sup>†</sup> at Baseline for High Risk Patients (Top 25%)

| Patient Characteristics       | Placebo<br>N = 312 | Mirabegron 50 mg<br>N = 328 |
|-------------------------------|--------------------|-----------------------------|
| Age, yrs (Mean, [SD])         | 70 (8)             | 70 (8)                      |
| AM SBP, mmHg (Mean, [SD])     | 142 (17)           | 142 (17)                    |
| Gender, M/F                   | 213/99             | 226/102                     |
| Antihypertensive Treatment, % | 68                 | 67                          |
| Diabetes Status, %            | 22                 | 23                          |
| 10-year CVD Risk (Median)     | 31%                | 31%                         |

<sup>†</sup>Total and High-Density Lipoprotein Cholesterol, and Smoking Status not collected in Phase III programs. Imputed based on age and sex

# Potential for Increase in CVD Risk with Mirabegron Based on Phase III SBP<sup>†</sup> Effect

<sup>†</sup> Maximum mean change in AM SBP post-baseline (at trough)

## Summary of Case Study 3

- Benefit-risk assessment performed to evaluate the appropriateness of 50 mg QD dose
  - Based on the phase III data, the 50 mg QD is the lowest dose that has consistently demonstrated significant efficacy in OAB patients.
  - Based on the Phase I and Phase III data, there is evidence mirabegron increases BP.
  - Assessment of these relationships led to approval of 25 mg dose, which was only evaluated in a single Phase III trial.

## Take Home Messages

- **Exploratory (e.g. Pharmacometrics) analyses are often used to make regulatory decisions**
  - Drug Approval and Labeling are two key decisions
    - Decisions are not entirely driven by the pre-specified analysis
  - Trial Design
  - Quantitative Risk Benefit
- **Decisions occur at all phases of development**
  - Early communication helps ensure the best possible outcome

# Division of Pharmacometrics (2013)
